Multiple myeloma treatment market to reach \$8.9 bn by 2021, analyst

Singapore: Global multiple myeloma treatment market value will expand from \$7.3 billion in 2014 to \$8.9 billion by 2021, representing a moderate compound annual growth rate (CAGR) of 4.6 percent, according to analysis provider GBI Research.

According to the analysis, the growth will occur in markets of US, UK, France, Germany, Italy, Spain, Japan and Canada, driven primarily by rising multiple myeloma prevalence as a result of an aging population.

Additionally, approvals during the forecast period for drugs that will supplement current market leaders, such as Revlimid, and offer improved therapeutic options, mainly in the relapsed/refractory setting, will also boost the market. Promising examples include ixazomib, ARRY-520 (filanesib), elotuzumab and daratumumab.

Mr Yasser Mushtaq, senior analyst, GBI Research, said, "Although multiple myeloma remains incurable, greater understanding of its underlying cellular and molecular biology has driven novel therapy development, with clinical outcomes improving significantly as a result.

"While some late-stage pipeline drugs will have a low impact, others have demonstrated promising clinical results in specific patient populations, including elotuzumab and daratumumab. These products are therefore likely to provide physicians with increased choice and complexity in multiple myeloma treatment over the forecast period."

However, the analyst added that various market barriers, such as a limited target patient population, will restrict any further growth in the multiple myeloma therapeutics arena by 2021.

Mr Mushtaq explained, "Multiple myeloma's rarity and designation as an orphan disease limits the available treatment

population, in turn hindering the potential revenues that can be generated from this indication. This, combined with high drug development costs, can deter manufacturers from investing in this area."

"On the other hand, incentives for orphan disease drug development, along with the ability to reposition drugs from one indication to another, could help to counter these challenges and drive further research into multiple myeloma treatment," the analyst concluded.
